NEW QUESTION: 4
Which of the following password attacks is MOST likely to crack
the largest number of randomly generated
passwords?
A. Birthday attack
B. Dictionary
C. Rainbow tables
D. Hybrid
Answer: C
Explanation:
Section: Threats and Vulnerabilities
Explanation/Reference:
Explanation:
When a password is "tried" against a system it is "hashed"
using encryption so that the actual password is
never sent in clear text across the communications line. This
prevents eavesdroppers from intercepting the
password. The hash of a password usually looks like a bunch of
garbage and is typically a different length
than the original password. Your password might be "shitzu" but
the hash of your password would look
something like "7378347eedbfdd76161945194925ec1".
To verify a user, a system takes the hash value created by the
password hashing function on the client
computer and compares it to the hash value stored in a table on
the server. If the hashes match, then the
user is authenticated and granted access.
Password cracking programs work in a similar way to the login
process. The cracking program starts by
taking plaintext passwords, running them through a hash
algorithm, such as MD5, and then compares the
hash output with the hashes in the stolen password file. If it
finds a match, then the program has cracked
the password.
Rainbow Tables are basically huge sets of precomputed tables
filled with hash values that are pre-
matched to possible plaintext passwords. The Rainbow Tables
essentially allow hackers to reverse the
hashing function to determine what the plaintext password might
be.
The use of Rainbow Tables allows for passwords to be cracked in

a very short amount of time compared
with brute-force methods, however, the trade-off is that it
takes a lot of storage (sometimes Terabytes) to
hold the Rainbow Tables themselves.
With a rainbow table, all of the possible hashes are computed
in advance. In other words, you create a
series of tables; each has all the possible two-letter,
three-letter, four-letter, and so forth combinations and
the hash of that combination, using a known hashing algorithm
like SHA-2. Now if you search the table for
a given hash, the letter combination in the table that produced
the hash must be the password you are
seeking.
